

## ivi bets

<p>A "farmer's tan" (also called "golfer's tan" or "tanned tan") is a type of tan that is caused by prolonged exposure to the sun, particularly in the face and neck. It is characterized by a dark, uneven tan that is most prominent on the face and neck, and is often associated with a sunburn. The tan is caused by the overexposure of the skin to ultraviolet radiation, which stimulates the production of melanin, the pigment that gives skin its color. The tan is most common in people who spend a lot of time outdoors, particularly in the summer months. It is also common in people who work in outdoor jobs, such as construction or agriculture. The tan is usually temporary and fades away over time, but it can be permanent if the skin is damaged by the sun. To prevent a farmer's tan, it is important to use sunscreen and wear protective clothing when outdoors.
